

Booking Cost Calculation

1. Overview

Within the **Availability** stage, a step named **Calculate Booking Cost** should be configured to determine the total cost of the movie ticket booking.

The calculation should use the **Ticket Price** and **Number of Tickets** properties to automatically derive the **Total Cost**.

2. Required Properties

The following properties are used for the calculation:

Property	Description
Ticket Price	Price of one movie ticket.
Number of Tickets	Number of tickets requested by the customer.
Total Cost	Calculated total price for all requested tickets.

3. Business Rule

A business rule should be configured to calculate the **Total Cost** automatically.

Formula:

Total Cost = Ticket Price × Number of Tickets

Example

If:

- Ticket Price = ₹200
- Number of Tickets = 3

Then:

Total Cost = ₹200 × 3 = ₹600

4. Automatic Calculation

The **Total Cost** field should be configured as a calculated field. Whenever the **Ticket Price** or **Number of Tickets** changes, the system should automatically recalculate the Total Cost.

This eliminates manual calculation and reduces pricing errors.

5. Store the Calculated Value

The calculated **Total Cost** should be stored within the **Movie Ticket Request** case. This ensures that the final booking cost is available for review in subsequent stages of the case.

6. Expected Outcome

After the Availability stage is completed, the case should contain an accurate **Total Cost** based on the selected ticket price and requested number of tickets.

Flow:

Ticket Price + Number of Tickets → Business Rule → Total Cost → Store in Case → Review Booking Cost
